Azurair™ B-Twin, based on the combination of two types of biological deodorizing equipment, can eliminate the olfactory nuisances of small wastewater treatment plants with no changes of media and without the use of reagents.

**innovation**
The pairing of two biological filters achieves a complete $\text{H}_2\text{S}$ treatment, and an advanced treatment of mercaptans.

Azurair™ B-Twin, based on the combination of two types of biological deodorizing equipment, can eliminate the olfactory nuisances of small wastewater treatment plants with no changes of media and without the use of reagents.

**Odor pollution control with a sustainable development approach**

- **ease of operation**
  
  Maintenance is reduced to the absolute minimum as the process does not require any reagents or any change of media.

- **environment**
  
  A 100% biological solution based on an entirely natural process.

**Key figure**

- 95% of $\text{H}_2\text{S}$ and mercaptans removed
Azurair™ B-Twin technology . . .

Hydrogen sulfide (H₂S) and mercaptans are among the common pollutants at a wastewater treatment plant that are characterized as foul-smelling. The Azurair™ B technology developed by SUEZ, can eliminate up to 99% of the H₂S, and offers an efficient biological solution to the nuisances caused by hydrogen sulfide (health risks, corrosion of concrete and metals of sewerage structures). By pairing two Azurair™ B systems, and thereby creating the Azurair™ B-Twin, SUEZ has advanced the 100% biological deodorization of treatment facilities by simultaneously addressing the treatment of H₂S and mercaptans (R-SH). This combination provides a comprehensive odor treatment solution.

A reinforced treatment process: Azurair™ B-Twin is based on a system of biological deodorization carried out in two sequential towers, adhering to the principle of the streaming biofilter: the towers are both equipped with a mineral media (biolite) to which micro-organisms are attached that have the special property of breaking down the odor-causing compounds via their metabolism. In order to optimize the breakdown of these pollutants, a sequential sprinkling system is integrated, maintaining an optimal moisture content.

. . . what it can do for you

The foul air is introduced into the first tower and goes through the first acidic pH biofilter which promotes the elimination of H₂S before being directed to the second tower (or "finishing tower") which functions at a neutral pH to facilitate the elimination of mercaptans, with no use of reagents or regulation.

environment and safety
- a 100% biological solution
- no use of chemical reagents
- compact equipment
- elimination of risks linked to H₂S

performance and savings
- efficient treatment of H₂S and mercaptans
- investment and operating costs that are superior to other air treatment technologies

ease of operation
- continuous-use mineral media (does not require replacement or reloading)
- natural process that does not require regulation
